**ABSTRACT**

INTRODUCTION: The definition of severe recurrent throat infections is arbitrary, but recent criteria have defined severe tonsillitis as: five or more episodes of true tonsillitis a year; symptoms for at least 1 year; and episodes that are disabling and prevent normal functioning. Diagnosis of acute tonsillitis is clinical, and it can be difficult to distinguish viral from bacterial infections. Rapid antigen testing has a very low sensitivity in the diagnosis of bacterial tonsillitis, but more accurate tests take longer to deliver results. Bacteria are cultured from few people with tonsillitis. Other causes include infectious mononucleosis from Epstein-Barr virus infection, cytomegalovirus, toxoplasmosis, HIV, hepatitis A, and rubella.

METHODS AND OUTCOMES: We conducted a systematic review and aimed to answer the following clinical question: What are the effects of tonsillectomy in children and adults with acute recurrent or chronic throat infections? We searched: Medline, Embase, The Cochrane Library, and other important databases up to April 2014 (Clinical Evidence reviews are updated periodically; please check our website for the most up-to-date version of this review). We included harms alerts from relevant organisations such as the US Food and Drug Administration (FDA) and the UK Medicines and Healthcare products Regulatory Agency (MHRA).

RESULTS: We found 15 studies that met our inclusion criteria. We performed a GRADE evaluation of the quality of evidence for interventions.

CONCLUSIONS: In this systematic review, we present information relating to the effectiveness and safety of the following interventions: cold-steel tonsillectomy and diathermy tonsillectomy.

**QUESTIONS**

What are the effects of tonsillectomy in children and adults with acute recurrent or chronic throat infections? . . . 3

**INTERVENTIONS**

| Beneficial | Cold-steel tonsillectomy (better peri- and postoperative outcomes than diathermy tonsillectomy in adults and children) | 3 |
| Trade off between benefits and harms | Tonsillectomy (reduces tonsillitis in children compared with no surgery but associated with morbidity) | 6 |
| | Tonsillectomy (may reduce sore throat frequency in adults compared with no surgery but is associated with morbidity) | 10 |

**Key points**

- Diagnosis of acute tonsillitis is clinical, and it can be difficult to distinguish viral from bacterial infections.
  
  Rapid antigen testing has a very low sensitivity in the diagnosis of bacterial tonsillitis, but more accurate tests take longer to deliver results.
  
  Bacteria are cultured from few people with tonsillitis. Other causes include infectious mononucleosis from Epstein-Barr virus infection, cytomegalovirus, toxoplasmosis, HIV, hepatitis A, and rubella.
  
- Acute tonsillitis with group A beta-haemolytic streptococci can occasionally cause rheumatic fever and acute glomerulonephritis, which can be prevented by treatment with penicillin.
  
  In resource-rich countries, these complications are so rare that routine aggressive antibiotic use cannot be justified.
  
- Tonsillectomy, with or without adenoidectomy, is one of the most frequently performed surgical procedures in the UK.
  
  In adults, we found limited evidence from one small RCT that surgery may reduce sore throats at 5 to 6 months, but we found no longer-term evidence. Tonsillectomy may be associated with morbidity.
  
- In children, the effectiveness of tonsillectomy has to be judged against the potential harms. Tonsillectomy is more beneficial in children with severe symptoms, while in populations with a low incidence of tonsillitis, the modest benefit may be outweighed by the morbidity associated with the surgery.
  
- The use of diathermy in tonsillectomy in adults or children is associated with reduced rates of primary bleeding, but increased rates of secondary and overall bleeding.

- Overall, cold-steel dissection tonsillectomy seems to have the lowest rates of postoperative haemorrhage and pain, although it is associated with slightly increased intra-operative bleeding. The use of diathermy in tonsillectomy must be weighed against its potential harms.

  Adequate training in the appropriate use of diathermy during tonsillectomy is important. In deciding which method to apply, the surgeon should consider the underlying characteristics of patients, as well as the relative importance of secondary compared with primary bleeding and intra-operative blood loss compared with postoperative pain.
episodes that are disabling and prevent normal functioning.\(^1\) However, in most cases, the severity of recurrent throat infections depends on many factors and cannot be judged solely on the basis of its incidence. This definition does not include tonsillitis caused by infectious mononucleosis, which usually occurs as a single episode. However, acute tonsillitis in this situation may be followed by recurrent tonsillitis in some people. Tonsillitis may occur in isolation or as part of a generalised pharyngitis. The clinical distinction between tonsillitis and pharyngitis is unclear in the literature, and the condition is often referred to simply as ‘acute sore throat’. A sore throat lasting for 24 to 48 hours as part of the prodrome of minor upper respiratory tract infection is excluded from this definition. Diagnosis of acute tonsillitis is primarily clinical, with the main interest being in whether the illness is viral or bacterial — this being of relevance if antibiotics are being considered. Studies have attempted to distinguish viral from bacterial sore throat on clinical grounds, but the results are conflicting, suggesting a lack of reliable diagnostic criteria. Investigations to assist with this distinction include throat swabs and serological tests, including the rapid antigen test and the anti-streptolysin O titre. Rapid antigen testing is convenient and popular in North America, but has doubtful sensitivity (61%–95%), at least when measured against throat swab results, although specificity is higher (88%–100%).\(^1\) However, the inevitable delay in reporting of both swabs and the anti-streptolysin O titre reduce their value in the routine clinical situation.

### INCIDENCE/PREVALENCE

Recurrent sore throat has an incidence in general practice in the UK of 100 per 1000 population per year.\(^2\) Acute tonsillitis is more common in childhood.

### AETIOLOGY/RISK FACTORS

Common bacterial pathogens include beta-haemolytic and other streptococci. Bacteria are cultured from only a minority of people with tonsillitis. The role of viruses is uncertain. In tonsillitis associated with infectious mononucleosis, the most common infective agent is the Epstein-Barr virus (present in 50% of children and 90% of adults with the condition). Cytomegalovirus infection may also result in the clinical picture of infectious mononucleosis, and the differential diagnosis also includes toxoplasmosis, HIV, hepatitis A, and rubella.\(^5\)

### PROGNOSIS

We found no good data on the natural history of tonsillitis or recurrent sore throat in children or adults. People in RCTs randomised to medical treatment (courses of antibiotics as required) have shown a tendency towards improvement over time.\(^4\)\(^5\)\(^6\)\(^7\)\(^8\) Recurrent severe tonsillitis results in considerable morbidity,\(^3\) including time lost from school or work. The most common complication of acute tonsillitis is peritonsillar abscess, but we found no good evidence on its incidence. Rheumatic fever and acute glomerulonephritis are recognised complications of acute tonsillitis associated with group A beta-haemolytic streptococci. These diseases are rare in resource-rich countries, but do occasionally occur. They are still a common problem in certain populations, notably Australian aboriginal people, and may be effectively prevented in closed communities by the use of penicillin. A systematic review found that antibiotics reduced the incidence of these diseases.\(^10\) However, in resource-rich countries, these diseases are so rare that routine aggressive antibiotic use is not justified. The review also found that antibiotics shorten the duration of illness by about 16 hours overall.\(^10\)

### AIMS OF INTERVENTION

To abolish tonsillitis; to reduce the frequency and severity of recurrent throat infections; to improve general wellbeing, behaviour, and educational achievement, with minimal adverse effects.

### OUTCOMES

For all options, we report: episodes of tonsillitis or sore throat (includes analgesia for tonsillitis or sore throat and antibiotic use); and time off school or work. For options comparing surgical techniques versus each other, we also report: surgery: bleeding (intra-operative and postoperative), and surgery: postoperative pain (includes analgesia use for pain from surgery).

### METHODS

Clinical Evidence search and appraisal April 2014. The following databases were used to identify studies for this systematic review: Medline 1966 to April 2014, Embase 1980 to April 2014, and The Cochrane Database of Systematic Reviews 2014, issue 4 (1966 to date of issue). Additional searches were carried out in the Database of Abstracts of Reviews of Effects (DARE) and the Health Technology Assessment (HTA) Database. We also searched for retractions of studies included in the review. Titles and abstracts identified by the initial search, run by an information specialist, were first assessed against predefined criteria by an evidence scanner. Full texts for potentially relevant studies were then assessed against predefined criteria by an evidence analyst. Studies selected for inclusion were discussed with an expert contributor. All data relevant to the review were then extracted by an evidence analyst. Study design criteria for inclusion in this review were: published systematic reviews and RCTs in English language, at least single-blinded, and containing >20 individuals of whom >80% were followed up. There was no minimum follow-up for cold-steel tonsillectomy versus diathermy tonsillectomy. There was a minimum length of follow-up of 6 months to 1 year for tonsillectomy versus no surgery in adults or children. For this comparison, we have preferentially reported outcomes at 1 year where they have been reported. We excluded
all studies described as ‘open’, ‘open label’, or not blinded unless blinding was impossible. We included RCTs and systematic reviews of RCTs, where harms of an included intervention were assessed, applying the same study design criteria for inclusion as we did for benefits. In addition, we use a regular surveillance protocol to capture harms alerts from organisations such as the FDA and the MHRA, which are added to the reviews as required. To aid readability of the numerical data in our reviews, we round many percentages to the nearest whole number. Readers should be aware of this when relating percentages to summary statistics such as relative risks (RRs) and odds ratios (ORs). We have performed a GRADE evaluation of the quality of evidence for interventions included in this review (see table, p 14). The categorisation of the quality of the evidence (high, moderate, low, or very low) reflects the quality of evidence available for our chosen outcomes in our defined populations of interest. These categorisations are not necessarily a reflection of the overall methodological quality of any individual study, because the Clinical Evidence population and outcome of choice may represent only a small subset of the total outcomes reported, and population included, in any individual trial. For further details of how we perform the GRADE evaluation and the scoring system we use, please see our website (www.clinicalevidence.com).

QUESTION What are the effects of tonsillectomy in children and adults with acute recurrent or chronic throat infections?

OPTION COLD-STEEL TONSILLECTOMY VERSUS DIATHERMY TONSILLECTOMY

• For GRADE evaluation of interventions for Tonsillitis, see table, p 14.

• The use of diathermy in tonsillectomy in adults or children is associated with reduced rates of primary bleeding but increased rates of secondary and overall bleeding.

• Overall, cold-steel dissection tonsillectomy seems to have the lowest rates of postoperative haemorrhage and pain, although it is associated with slightly increased intra-operative bleeding.

• Adequate training in the appropriate use of diathermy during tonsillectomy is important. In deciding which method to apply, the surgeon should consider the underlying characteristics of patients, as well as the relative importance of secondary compared with primary bleeding and intra-operative blood loss compared with postoperative pain.

Benefits and harms

Cold-steel tonsillectomy versus diathermy tonsillectomy:

We found two systematic reviews of RCTs (search date 2010, 2 RCTs; [11] and search date 2001, 6 RCTs), [12] both of which reported information on only complications of surgery. We also found one systematic review of observational data reporting on bleeding rates associated with surgery (see Comment). [13] We found two additional RCTs, [14] [15] and one subsequent RCT. [16]

Surgery: bleeding

Cold-steel tonsillectomy compared with diathermy tonsillectomy Cold-steel tonsillectomy may be associated with a higher rate of intra-operative blood loss, but we don’t know which technique is associated with a lower risk of secondary bleeding (very low-quality evidence).

### Time off school or work

No data from the following reference on this outcome.\[11\]  \[12\]  \[14\]  \[15\]  \[16\]

#### Further information on studies

[\[12\] The review found that diathermy tonsillectomy reduced operative time (mean time per tonsil: 2.5 minutes with diathermy v 6.0 minutes with cold-steel; significance not assessed).

**Comment:**

One systematic review (50 studies consisting of 10 RCTs, 15 non-randomised comparative studies, 14 case series, and 11 within-patient studies, as well as the population-based registry reports, from the Wales Single-use Instrument Surveillance Programme [3690 people] and the England and Northern Ireland National Prospective Tonsillectomy Audit [33,921 people]) evaluated the evidence for electrosurgery (diathermy or coblation) for tonsillectomy in children and adults, particularly in respect of rates of haemorrhage.\[15\]  

The review found that electrosurgery (coblation or diathermy dissection and haemostasis) was associated with higher rates of secondary bleeding (including haemorrhage requiring return to theatre) compared with cold-steel dissection with haemostasis with ties or packs. Cold-steel dissection was associated with higher rates of primary bleeding including return to theatre. Cold-steel dissection using ties or packs for haemostasis was associated with the lowest overall rate of postoperative bleeding (1.7%–2.0%); cold-steel dissection with bipolar diathermy haemostasis was associated with the lowest rate of haemorrhage requiring return to theatre (0%–0.7%).

**Clinical guide:**

Adequate training in the appropriate use of diathermy during tonsillectomy is important. In deciding which method to apply, the surgeon should consider the underlying characteristics of patients, as well as the relative importance of secondary compared with primary bleeding and intra-operative blood loss compared with postoperative pain. Overall, cold-steel dissection tonsillectomy seems to have the lowest rates of postoperative haemorrhage and pain, although it is associated with slightly increased intra-operative bleeding. The use of diathermy in tonsillectomy must be weighted against its potential harms.

---

**OPTION TONSILLECTOMY VERSUS NO SURGERY IN CHILDREN**

- For GRADE evaluation of interventions for Tonsillitis, see table, p 14.
- In children, the effectiveness of tonsillectomy has to be judged against the potential harms.
- Tonsillectomy is more beneficial in children with severe symptoms, while in populations with a low incidence of tonsillitis, the modest benefit may be outweighed by the morbidity associated with the surgery.
- Tonsillectomy is associated with intra-operative and postoperative morbidity, including haemorrhage, while antibiotics are associated with adverse effects, such as rash.
**Benefits and harms**

**Tonsillectomy versus no surgery in children:**

We found three systematic reviews (search dates 1998, 2003, and 2008), [17] [18] [19] which identified seven RCTs in total. We found one subsequent RCT. [20]

### Episodes of tonsillitis or sore throat

**Tonsillectomy compared with non-surgical treatment**

Tonsillectomy may reduce the frequency of tonsillitis episodes in children (very low-quality evidence).

### Results and statistical analysis

#### Incidence rate ratio

- **Incidence rate ratio 0.67**
  - 95% CI 0.52 to 0.85
  - The study also reported mean episodes of sore throats per month and found similar results.

#### Mean number of days of sore throat

- **Mean number of days of sore throat, year 1**
  - 31.0 with surgery (tonsillectomy and adenotonsillectomy with adenoid curettage and tonsillectomy by dissection or bipolar diathermy)
  - 49.1 with no surgery (conventional medical treatment only)

- **Mean number of days of sore throat, year 2**
  - 8.0 with surgery (tonsillectomy and adenotonsillectomy with adenoid curettage and tonsillectomy by dissection or bipolar diathermy)
  - 20.2 with no surgery (conventional medical treatment only)

#### Mean number of days of sore throat (adjusted)

- **Mean number of days of sore throat (adjusted)**
  - 2.8 days per person-year
  - 95% CI ~3.9 days per person-year to ~1.6 days per person-year

#### Incidence rate ratio (adjusted)

- **Incidence rate ratio 0.27**
  - 95% CI 0.16 to 0.46

#### Adjusted least squares regression

- **Adjusted least squares regression over the 2 years demonstrated a significant reduction in sore throat episodes (mean): 5.5 with surgery v 9.0 with no surgery, MD 3.5, 95% CI 1.8 to 5.2**

---

Further information on studies

[17] The authors of the review noted high potential for bias in the RCTs they identified. Inclusion criteria in some of the older trials were not strictly defined, and encompassed upper respiratory tract infections, cervical adenitis, or 'children who would normally be placed in waiting list for adenotonsillectomy'.

[18] Variation in severity of tonsillitis: three of the RCTs in the review (346 children) examined children with severe recurrent tonsillitis. One RCT looked at children with milder symptoms; 52% of those had tonsillectomy for indications other than recurrent throat infection. Children in both groups of the identified RCTs received antibiotics as needed for throat infections. Review conclusions: the review concluded that adenotonsillectomy or tonsillectomy would avoid one unpredictably timed episode of moderate or severe sore throat in more severely affected children in the first year post-surgery, at a cost of a predictable episode of pain in the immediate postoperative period.

[19] The benign natural course of recurrent tonsillitis in children was demonstrated as children in the control group having had fewer episodes of sore throats during the follow-up period than before study entry (no absolute figures or significance assessment reported). However, in all of the included studies, the most severely affected children either opted for surgery or (in the earlier studies) were allocated to surgery, which may have resulted in an underestimation of treatment effect. In addition, the included studies assessed adenotonsillectomy, rather than tonsillectomy alone, and all RCTs and non-randomised trials had significant methodological limitations. Taking this into account, the authors of the review concluded that surgery provided an additional but small reduction in sore throat episodes and sore throat-associated school absence compared with no surgery.

[6] One child suffered anaesthetic induction trismus and possible incipient malignant hyperthermia; three children had intra-operative haemorrhage, with one of them needing re-intervention under anaesthesia; and one child required a posterior nasopharyngeal pack and admission to intensive care. Seven children (3%) developed postoperative haemorrhage, and five of these were re-admitted to hospital, one requiring transfusion. The mean duration of postoperative sore throat was 6.3 days (range 0–21 days).
The selection criteria were changed midway through the study from 'children with mild symptoms having six or more episodes in 2 years or eight or more episodes in 1 year, or children with moderate symptoms (sore throat for 5 days or more) having six or more episodes in 1 or 2 years' to 'children with four or more episodes of sore throat within each of 2 years or six or more episodes of sore throat within 1 year'. The criteria for defining episodes of sore throat were: minimum number of consecutive days on which a sore throat is recorded that can constitute an episode is 3 with no maximum number of consecutive days; any consecutive recording of sore throat interrupted by 4 days of non-recording constituted a new episode; periods of sore throat separated in time by less than 4 days with no recording of sore throat were pooled before application of the previous criteria.

Comment: Antibiotics:
One RCT (716 people with sore throat and an abnormal physical sign) found that the prescribing of antibiotics compared with no initial prescription significantly increased the proportion of people who returned to see their physician in the short term because of sore throat (return rate: 38% with initial antibiotics v 27% without initial antibiotics; adjusted HR for return 1.39, 95% CI 1.03 to 1.89).

Clinical guide:
Tonsillectomy is one of the most frequently performed surgical procedures in the UK, particularly in children, and accounts for about 20% of all operations performed by otolaryngologists. Adenoidectomy is now performed with tonsillectomy in the UK only when there is a specific indication to remove the adenoids as well as the tonsils (32% of cases), although it remains common practice in both Europe and North America to combine the operations (the Netherlands: 90% of cases; USA: 84% of cases; and Canada: 75% of cases).

Decades of experience of using tonsillectomy for recurrent or severe throat infections in children have led to consensus that it is effective. However, it is suggested that the effectiveness of tonsillectomy has to be weighed against its potential harms. One Scottish tonsillectomy audit found that tonsillectomy was associated with a overall complication rate of 2% to 8%; less than 1% of children had primary haemorrhage (in the immediate postoperative period) or secondary haemorrhage. Tonsillectomy results in a greater benefit in children with severe symptoms; for those with less severe symptoms, benefits must be judged (a reduction of approximately one episode, and 4 days' duration of sore throat in the first year) in light of the morbidity of surgery (one predictable episode of sore throat that can typically last 6 days).

We found no RCTs that found improved general wellbeing, development, or behaviour, despite suggestions that these are influenced by tonsillectomy. We found no RCTs addressing long-term effects of tonsillectomy.

Option 1

Tonsillectomy versus no surgery in adults:

- For GRADE evaluation of interventions for Tonsillitis, see table, p 14.
- We found limited evidence from one small RCT that surgery may reduce sore throats at 5 to 6 months, but we found no longer term evidence.
- Tonsillectomy is associated with intra-operative and postoperative morbidity, including haemorrhage.

Tonsillectomy compared with no surgery in adults:
We found one systematic review (search date 2008), which identified one RCT in adults.

Episodes of tonsillitis or sore throat
Tonsillectomy may be more effective at reducing the frequency and duration of sore throat at 5 to 6 months, but we don't know the long-term effects (low-quality evidence).

**Comment:** Clinical guide: Data from one good-quality RCT (albeit with limited follow-up) confirm the consensus that tonsillectomy is an effective treatment for adults with severe recurrent sore throat, and that it should be offered to patients, unless there are contra-indications, despite the absence of strong evidence from RCTs.
Glossary

Low-quality evidence Further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.

Very low-quality evidence Any estimate of effect is very uncertain.

Substantive Changes

Cold-steel tonsillectomy versus diathermy tonsillectomy One systematic review updated (2 RCTs, search date 2010). Three RCTs added. Categorisation unchanged (beneficial).

Tonsillectomy versus no surgery in children One RCT added. Categorisation unchanged (trade-off between benefits and harms).

We initially allocate 4 points to evidence from RCTs, and 2 points to evidence from observational studies. To attain the final GRADE score for a given comparison, points are deducted or added from this initial score based on preset criteria relating to the categories of quality, directness, consistency, and effect size. Quality: based on issues affecting methodological rigour (e.g., incomplete reporting of results, quasi-randomisation, sparse data [<200 people in the analysis]). Consistency: based on similarity of results across studies. Directness: based on generalisability of population or outcomes. Effect size: based on magnitude of effect as measured by statistics such as relative risk, odds ratio, or hazard ratio.
